Prepared in partial fulfilment of the

Project-Based Learning of course CSE 205 – Hands On With Python

SRM UNIVERSITY AP

APRIL 2026.

CERTIFICATE

This is to certify that the project entitled Titanic Survival Statistical Analysis has been completed by Budigam Nishwitha (AP241100**10759**), a**s** a required academic component of the course **CSE 205:** Hands On With Python during **Semester 4** of Academic Year 2025 – 2026 in the Department of Computer Science and Engineering at SRM university AP. This work was executed under the guidance of the undersigned and is deemed to have successfully met all course requirements as of April 2026.

ABSTRACT

The *Titanic Survival Statistical Analysis* project focuses on exploring and analyzing passenger data from the historic RMS Titanic sinking to uncover patterns and factors that influenced survival outcomes. Using a structured dataset containing 891 passenger records and 12 attributes such as age, gender, passenger class, fare, and family relations, this study applies statistical and programming techniques to derive meaningful insights.The program is designed using Python and follows a modular approach with robust error handling mechanisms to ensure smooth data loading and processing. Initial steps involve data exploration, including viewing dataset structure, identifying anomalies, and handling missing values—particularly in the Age and Fare columns—through logical conditions and manual computations. New derived features such as *Family Size*, *Fare Per Person*, and *Child Indicator* are created to enhance analytical depth.

A key focus of the analysis is the "Women and Children First" principle, where logical and relational operations are used to compare survival rates between prioritized groups and others. The project further incorporates random sampling techniques to compare survivors and non-survivors based on statistical measures like average age, fare, and family size.Comprehensive statistical analysis is performed using both built-in pandas functions and manual implementations involving loops, recursion, and functional programming constructs such as map(), filter(), and reduce(). Group-based insights are generated across categories like gender, passenger class, and port of embarkation.

Finally, the results are compiled into a detailed report file, providing a clear summary of findings and interpretations. This project not only demonstrates data analysis skills but also emphasizes core programming concepts, making it a complete integration of statistics, logic building, and practical data science techniques.

OBJECTIVE

- To load and preprocess the Titanic dataset using robust error-handling techniques.
- To explore and analyze passenger data such as age, gender, class, fare, and family relationships.
- To identify and handle missing or inconsistent data using logical and statistical methods.
- To create new meaningful features like *Family Size*, *Fare Per Person*, and *Is Child* to enhance analysis.
- To evaluate the "Women and Children First" hypothesis using logical and relational operations.
- To compare survivors and non-survivors using random sampling and statistical measures.
- To compute descriptive statistics (mean, median, mode, min, max) manually and using pandas.
- To apply functional programming concepts such as map(), filter(), and reduce() in data processing.
- To generate a detailed analytical report summarizing key findings and insights.

METHODOLOGY

- Data Loading with Error Handling
- Data Exploration
- Handling Missing Values
- Feature Engineering
- Women & Children Analysis
- Sampling and Comparative Study
- Statistical Computation
- unctional Programming
- Report Generation

INTRODUCTION

The sinking of the RMS Titanic is one of the most tragic and widely studied maritime disasters in history. On its maiden voyage in April 1912, the "unsinkable" ship struck an iceberg in the North Atlantic and sank, resulting in the deaths of more than 1,500 passengers and crew. While the event is often remembered for its scale, it also serves as a profound case study in how social class, gender, and age influenced the likelihood of survival in a moment of extreme crisis.

This project uses the Titanic passenger dataset as a foundation for a detailed statistical analysis. The dataset consists of 891 individual records, each containing variables that describe the demographic and socio-economic status of the passengers. These attributes include passenger class (Pclass), gender (Sex), age, fare paid, family relations (siblings, spouses, parents, and children), and the port of embarkation. By examining these features, we can uncover patterns that reveal the hidden social dynamics of the early 20th century.

The primary objective of this analysis is to identify which factors significantly contributed to a passenger's survival. Special emphasis is placed on evaluating the "Women and Children First" maritime tradition and the survival gaps between different ticket classes. Furthermore, the study explores how family size and ticket fare impacted survival probability, testing the hypothesis that wealth and social standing afforded certain passengers a higher chance of escape.

From a technical perspective, this study combines statistical analysis with fundamental Python programming. The workflow involves significant data preprocessing, such as treating missing values (particularly in the 'Age' and 'Cabin' columns) and creating new features to enhance the accuracy of the insights. By applying both manual statistical calculations and modern library-based methods, this project demonstrates how data-driven techniques can be used to interpret complex historical events and provide a deeper understanding of human survival patterns.

PROBLEM STATEMENT

The sinking of the RMS Titanic is a significant historical event that provides a window into the socio-economic and demographic hierarchies of the early 20th century. While the general narrative of the disaster is well-known, there remains a need to quantitatively analyze how specific passenger attributes—such as social class, gender, age, and family structure—statistically influenced survival outcomes.
The core problem addressed in this study is to identify and measure the factors that determined survival among the 891 passengers documented in the Titanic dataset. Despite the chaotic nature of the disaster, survival was not random.

However, several questions remain that require systematic data analysis:

1. **Socio-Economic Disparity:** To what extent did passenger class (Pclass) and the fare paid (Fare) influence a passenger's likelihood of reaching a lifeboat?
2. **The "Women and Children First" Protocol:** How strictly was this maritime tradition followed, and was gender a more significant predictor of survival than social class?
3. **Demographic Vulnerability:** Did the age of the passenger significantly impact their chances, and were children across all classes treated with the same priority?
4. **Family Dynamics:** Did traveling with family members (SibSp and Parch) provide a support system that increased survival, or did it hinder evacuation efforts?
5. **Data Integrity and Engineering:** How can missing data (such as null values in 'Age' and 'Cabin') be managed to ensure the statistical findings are robust and accurate?

Overall,this project aims to bridge the gap between historical anecdotes and data-driven insights. The goal is to provide a comprehensive model of survival that quantifies how human-made social structures persisted even in the face of a natural catastrophe.

DATASET DETAILS

The dataset used in this project is the **Titanic Passenger Manifest**, which contains demographic and travel information for 891 passengers. It serves as a foundation for analyzing the factors that contributed to survival during the 1912 disaster.

Dataset Format :

- **File Type:** CSV (Comma-Separated Values)
- **Delimiter Used:** Comma (,)
- **Nature:** Structured historical dataset

Key Attributes in the Dataset

Attribute	Description
Survived	Survival status (0 = No, 1 = Yes); the target variable.
Pclass	Passenger ticket class (1 = 1st, 2 = 2nd, 3 = 3rd).
Sex	Gender of the passenger (male/female).
Age	Age in years (includes fractional values for infants).
SibSp	Number of siblings or spouses aboard.
Parch	Number of parents or children aboard.
Fare	Price paid for the ticket.
Embarked	Port of embarkation (C = Cherbourg, Q = Queenstown, S = Southampton).

Dataset Characteristics

- The dataset contains a mix of **numerical** (Age, Fare, SibSp) and **categorical** (Sex, Embarked, Survived) variables.
- **Pclass** acts as an ordinal variable representing socio-economic status.
- The dataset contains missing values, specifically in the **Age** (177 missing), **Cabin** (687 missing), and **Embarked** (2 missing) columns, which are addressed during the preprocessing phase.
- The records represent a significant sample of the total passenger list, providing a robust basis for statistical inference.

Purpose of the Dataset:

This dataset is used to:

- Analyze the relationship between **social class** and survival probability.
- Understand the impact of the **"Women and Children First"** policy through gender and age analysis.
- Evaluate how **family size** (SibSp + Parch) influenced a passenger's ability to evacuate.
- Identify the correlation between **ticket fare** and access to life-saving resources.

Data Preprocessing Considerations

- **Missing Values:** Handled through imputation (e.g., filling missing ages with the median and embarked with the mode).
- **Data Transformation:** Created new meaningful features to deepen the analysis, such as:
    - **Family Size:** Combining SibSp and Parch to see the total number of relatives on board.
    - **Is Alone:** A binary feature indicating if a passenger was traveling without any family members.
    - **Title Extraction:** Identifying social titles (Mr., Mrs., Master., etc.) from the Name column to better estimate age and social status.

CODE SNIPPETS

```python
# ==============================================
# Titanic Survival Statistical Analysis Project
# ==============================================

import  pandas as pd
import random
from functools import reduce
```

1 . DATA LOADING WITH ERROR HANDLING

```python
# ---------------------------------------------
# 1. LOAD DATA WITH ERROR HANDLING
# ---------------------------------------------
def load_data(file_path):  1 usage
    try:
        df = pd.read_csv("titanic.csv")
        print("File loaded successfully!\n")
        return df
    except FileNotFoundError:
        print("Error::: File not found. Please check the file path.")
    except PermissionError:
        print("Error: Permission denied.")
    except Exception as e:
        print("Error:", e)
```

2 . DISPLAYING DATA

```
# ---------------------------------------------
# 2. DISPLAY DATA
# ---------------------------------------------
def display_data(df):  1 usage
    print("\nFirst 10 rows:\n", df.head(10))
    print("\nLast 5 rows:\n", df.tail(5))
    print("\nDataFrame Info:\n")
    print(df.info())

    print("\nPassengers older than 60 or in First Class:")
    for i in range(len(df)):
        if (df.loc[i, 'Age'] > 60) or (df.loc[i, 'Pclass'] == 1):
            print(df.loc[i])
```

3. HANDLING MISSING DATA

```
# ---------------------------------------------
# 3. HANDLE MISSING VALUES
# ---------------------------------------------
def fill_missing_values(df):  1 usage
    print("\nMissing values:\n", df.isnull().sum())

    # Fill Age manually using median of Pclass
    for pclass in [1, 2, 3]:
        ages = []
        for i in range(len(df)):
            if df.loc[i, 'Pclass'] == pclass and pd.notnull(df.loc[i, 'Age']):
                ages.append(df.loc[i, 'Age'])

        ages.sort()
        median_age = ages[len(ages)//2] if ages else 0

        for i in range(len(df)):
            if df.loc[i, 'Pclass'] == pclass and pd.isnull(df.loc[i, 'Age']):
                df.loc[i, 'Age'] = median_age

    # Treat zero fare as missing
    for i in range(len(df)):
        if df.loc[i, 'Fare'] == 0:
            df.loc[i, 'Fare'] = df['Fare'].median()

    return df
```

4. CREATING NEW COLUMNS

```python
# ------------------------------------------
# 4. CREATE NEW COLUMNS
# ------------------------------------------
def create_columns(df):  1 usage
    df['FamilySize'] = df['SibSp'] + df['Parch'] + 1

    fare_per_person = []
    for i in range(len(df)):
        try:
            value = df.loc[i, 'Fare'] / df.loc[i, 'FamilySize']
        except ZeroDivisionError:
            value = 0
        fare_per_person.append(value)

    df['FarePerPerson'] = fare_per_person

    df['IsChild'] = df['Age'] < 12

    return df
```

5. WOMEN AND CHILDREN ANALYSIS

```python
# ------------------------------------------
# 5. WOMEN & CHILDREN ANALYSIS
# ------------------------------------------
def women_children_analysis(df):  1 usage
    group1 = df[(df['Sex'] == 'female') | (df['Age'] < 12)]
    group2 = df[~((df['Sex'] == 'female') | (df['Age'] < 12))]

    print("\nWomen & Children Survival Rate:",
          group1['Survived'].mean())
    print("Others Survival Rate:",
          group2['Survived'].mean())

    # Manual check
    wc_survive = 0
    wc_total = 0

    for i in range(len(df)):
        if (df.loc[i, 'Sex'] == 'female') or (df.loc[i, 'Age'] < 12):
            wc_total += 1
            if df.loc[i, 'Survived'] == 1:
                wc_survive += 1

    print("Manual WC Survival Rate:", wc_survive / wc_total)
```

6. RANDOM SAMPLING

```python
# ----------------------------------------
# 6. RANDOM SAMPLING
# ----------------------------------------
def random_sampling(df):  1 usage
    survivors = df[df['Survived'] == 1].index.tolist()
    nonsurvivors = df[df['Survived'] == 0].index.tolist()

    sample_surv = random.sample(survivors, k: 50)
    sample_non = random.sample(nonsurvivors, k: 50)

    print("\nSample Survivors:")
    for i in sample_surv[:5]:
        print(df.loc[i])

    print("\nSample Non-Survivors:")
    for i in sample_non[:5]:
        print(df.loc[i])

    def avg(column, indices):
        return sum([df.loc[i, column] for i in indices]) / len(indices)

    print("\nAvg Age (Survivors):", avg( column: 'Age', sample_surv))
    print("Avg Age (Non-Survivors):", avg( column: 'Age', sample_non))
```

7.STATISTICS

```python
# ----------------------------------------
# 7. STATISTICS (MANUAL + PANDAS)
# ----------------------------------------
def recursive_sum(lst):  2 usages
    if len(lst) == 0:

CONCLUSION

The statistical analysis of the RMS Titanic dataset provides a profound look into the social dynamics and survival priorities during one of history's most significant maritime disasters. By applying both manual programming logic and library-based data manipulation, this project successfully quantified how specific attributes determined life or death in a moment of crisis.

1. **Validation of Social Hierarchy:** The data confirms a clear survival advantage for passengers in First Class. Despite having the same human needs as those in Third Class, higher socio-economic status directly correlated with a significantly higher survival rate, likely due to cabin location and priority access to lifeboats.
2. **Gender and Age as Primary Determinants:** The "Women and Children First" maritime tradition was statistically evident. The survival rate for the "Women and Children" group far exceeded that of adult males across all classes, proving that gender and age were the most powerful predictors of survival.
3. **Complexity of Family Dynamics:** Through feature engineering, the project revealed that family size played a nuanced role. While traveling with a small family unit appeared to improve survival chances (likely due to mutual assistance), traveling alone or with very large families (over 5 members) often led to lower survival probabilities.
4. **Technical Achievement:** From a computational perspective, the project demonstrated the power of Python in automating complex data tasks. By implementing manual loops, recursive summations, and functional programming (Map, Filter, Reduce), we ensured that the data was not only cleaned and imputed correctly but also analyzed with high precision.

In summary, the Titanic disaster was not an equal-opportunity tragedy. It was an event where pre-existing social structures and cultural norms dictated survival. This project illustrates how data science can be used to validate historical narratives and uncover the underlying patterns of human behavior in extreme circumstances.
